5pan(x, x23 = 5pan(v, x23 but V, 1 v2

of the upper triangular change-of-basis matrix R. X has dimension n x K and columns x_1, ..., x_K.

In (1), we first (a) create a orthogonal basis v_1, ..., v_K and then (b) normalize its component vectors into q_1, ..., q_K.

only a function of the y-vector

$$\vec{\hat{y}} = \vec{H} \vec{\hat{y}} = \mathbf{Q} \mathbf{V} \vec{\hat{y}} = \mathbf{\hat{y}} \mathbf{\hat{y$$

Pretend your friend gave you a new feature, i.e a new x-vector, $\vec{\chi}_{_g}$. You want to now update your OLS model to use it.

 $\times_{\mathbf{z}} = \left[\times \middle| \mathbf{x}_{\cdot *} \right]$

Now your friend says "btw, I made up that vector... it's just a bunch of random nonsense". Any new column vector in X would have the ostensible effect of improving your model. If that new column vector is independent of the true causal inputs to y (i.e. the z's), we call this "overfitting". Let's keep going. Your friend keeps supplying you with more and more garbage vectors. What happens when you have the same number of vectors p+1 = n? X_{\star} will be n x n and invertible so... \mathscr{B}_{\star}

 $H_{\mathbf{x}} = \mathbf{X}_{\mathbf{x}} \left(\mathbf{X}_{\mathbf{x}}^{\mathsf{T}} \mathbf{X}_{\mathbf{x}} \right)^{\mathsf{T}} \mathbf{X}_{\mathbf{x}}^{\mathsf{T}} = \mathbf{X}_{\mathbf{x}} \mathbf{X}_{\mathbf{x}}^{\mathsf{T}} \mathbf{X}_{\mathbf{x}}^{\mathsf{T}} \mathbf{X}_{\mathbf{x}}^{\mathsf{T}} = \mathbf{I}$

 $\vec{\hat{y}} = \vec{H}_{\kappa} \vec{\hat{y}} = \vec{\hat{y}} \Rightarrow \vec{\hat{e}} = \vec{\hat{o}}_{n} \Rightarrow SJE = 0 \Leftrightarrow R^{2} = 1 \Leftrightarrow RMJE = 0$ "Perfect f_{i+} " or "Maximal overfitting." How did we get into this mess? Consider a random vec x_random:

added fake fit (over-fit) (fake component of SSR) If you have a small number of features relative to n, it's not too bad (i.e. it won't reduce your predictive accuracy).

 $= R^{-1}R^{T^{-1}}R^{T}Q^{T}y = R^{-1}Q$
